You are currently looking at **version 1.0** of this notebook. To download notebooks and datafiles, as well as get help on Jupyter notebooks in the Coursera platform, visit the <u>Jupyter Notebook FAQ (https://www.coursera.org/learn/python-machine-learning/resources/bANLa)</u> course resource.

Applied Machine Learning, Module 1: A simple classification task

Import required modules and load data file

```
In [ ]: %matplotlib notebook
    import numpy as np
    import matplotlib.pyplot as plt
    import pandas as pd
    from sklearn.model_selection import train_test_split
    fruits = pd.read_table('fruit_data_with_colors.txt')

In [ ]: fruits.head()

In [ ]: # create a mapping from fruit label value to fruit name to make results easier to interpret
    lookup_fruit_name = dict(zip(fruits.fruit_label.unique(), fruits.fruit_name.unique()))
    lookup_fruit_name
```

The file contains the mass, height, and width of a selection of oranges, lemons and apples. The heights were measured along the core of the fruit. The widths were the widest width perpendicular to the height.

Examining the data

```
In [ ]: # plotting a scatter matrix
        from matplotlib import cm
        X = fruits[['height', 'width', 'mass', 'color score']]
        y = fruits['fruit label']
        X train, X test, y train, y test = train test split(X, y, random state=0)
        cmap = cm.get cmap('gnuplot')
        scatter = pd.scatter matrix(X train, c= y train, marker = 'o', s=40, hist kwds={'bins':15}, figsize=(9,9), cmap=0
In [ ]: # plotting a 3D scatter plot
        from mpl toolkits.mplot3d import Axes3D
        fig = plt.figure()
        ax = fig.add subplot(111, projection = '3d')
        ax.scatter(X train['width'], X train['height'], X train['color score'], c = y train, marker = 'o', s=100)
        ax.set_xlabel('width')
        ax.set ylabel('height')
        ax.set zlabel('color score')
        plt.show()
```

Create train-test split

```
In [ ]: # For this example, we use the mass, width, and height features of each fruit instance
X = fruits[['mass', 'width', 'height']]
y = fruits['fruit_label']

# default is 75% / 25% train-test split
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=0)
```

Create classifier object

```
In [ ]: from sklearn.neighbors import KNeighborsClassifier
knn = KNeighborsClassifier(n_neighbors = 5)
```

Train the classifier (fit the estimator) using the training data

```
In [ ]: knn.fit(X_train, y_train)
```

Estimate the accuracy of the classifier on future data, using the test data

```
In [ ]: knn.score(X_test, y_test)
```

Use the trained k-NN classifier model to classify new, previously unseen objects

```
In []: # first example: a small fruit with mass 20g, width 4.3 cm, height 5.5 cm
    fruit_prediction = knn.predict([[20, 4.3, 5.5]])
    lookup_fruit_name[fruit_prediction[0]]

In []: # second example: a larger, elongated fruit with mass 100g, width 6.3 cm, height 8.5 cm
    fruit_prediction = knn.predict([[100, 6.3, 8.5]])
    lookup fruit name[fruit prediction[0]]
```

Plot the decision boundaries of the k-NN classifier

```
In [ ]: from adspy_shared_utilities import plot_fruit_knn
plot_fruit_knn(X_train, y_train, 5, 'uniform') # we choose 5 nearest neighbors
```

How sensitive is k-NN classification accuracy to the choice of the 'k' parameter?

How sensitive is k-NN classification accuracy to the train/test split proportion?

In []:
